Abstract—
Objective: The present study was aimed to investigate analgesic and anti-diarrheal activities of ethanolic extracts of Swietenia mahagoni leaves using experimental models.

Methods: Analgesic activity of S. mahagoni leaves was tested by acetic acid-induced writhing test at a dose of 100 and 200 mg/kg and formalin-induced hind paw-licking at 150 and 300 mg/kg administered orally where Indomethacin (10 mg/kg) was used as a standard analgesic drug. Anti-diarrheal activity was investigated using castor oil-induced diarrhea through oral administration of extracts at a dosage of 250 and 500 mg/kg. Loperamide (5 mg/kg) was used as a standard drug in this method.

Results: In acetic acid-induced writhing test, ethanolic extract of S. mahagoni leaves showed maximum percentages of pain inhibition (56.14%) at 200 mg/kg dose in a dose-dependent manner where standard (Indomethacin) was 77.19%. The formalin-induced hind paw-licking test of S. mahagoni leaves showed 43.08% inhibition in early phase where standard (Indomethacin) was 76.92% and in the late phase, 34.88% inhibition at 300 mg/kg dose where standard (Indomethacin) was 58.14%. In castor oil-induced anti-diarrheal test, ethanolic extract of S. mahagoni leaves showed 98.89% inhibition at 250 mg/kg and 94.45% inhibition at 500 mg/kg dose which was exactly the same of standard (Loperamide) inhibition.

Conclusions: The current study indicates that ethanolic extract of S. mahagoni leaves have moderate analgesic and potential anti-diarrheal activity that support to the ethnopharmacological uses of this plant.

Keywords— Analgesic; Anti-diarrheal; Pain Inhibition; Swietenia mahagoni.

I. INTRODUCTION

For the management of pain and inflammation, either narcotic drugs e.g. opioids or non-narcotic drugs e.g. salicylates and corticosteroids are used at present [1] which are not fully satisfactory in all cases due to their adverse side effects, for example gastric lesions, ulcers, hypertension and cardiac abnormalities are caused by non-steroidal anti-inflammatory drugs and opiates [2,3]. Hence, development of newer analgesic drugs with lesser side effects is crucial. Large source of structurally novel compounds are available in medicinal plants that might help in the advancement of new drugs. According to World Health Organization (WHO), around 80% of the world’s population fulfills their primary health care needs by using traditional medicine. Since prehistoric period herbal medicine has been widely used due to their availability and safety [4]. Diarrheal disease is another common disease, responsible for the death of millions of people each year which is mostly prevalent in developing countries especially in children [5]. Most people in the developing countries depend on herbal drugs for the management of diarrhoea. For this reason, World Health Organization has encouraged using traditional medicines in the treatment and prevention of this disease [6].

Swietenia mahagoni (S. mahagoni) is a moderate to massive evergreen plant commonly known as “mahagni” in bengali which is one of the species of genus Swietenia and belongs to chinaberry family, Meliaceae. It is an endemic plant of West Indies and also known as West Indies mahogany, caoba, caoba, dominicana or acajou [7]. Different parts of this plant used traditionally for variety of diseases. The leaves have been used for Diarrhea, fever, cough, cold and catarrh. As an astringent for wound, Bark is used. The seed’s use found in leishmaniasis, abortion medicine, cancer, amoebiasis, coughs, chest pains, intestinal parasitism, hypertension, diabetes and malaria in Indonesia and also in skin cuts, itches and wounds to improve the healing process in African countries [8]. The uses of this plant as traditional medicine substantiate that it may contain some significant biological activities. Although Antibacterial activity [9,10], Antimicrobial Activity [11,9], Antioxidant activity [12], Cytotoxic activity [10], Anti-ulcer activity [13], Antifungal activity [14], Anti-HIV activity [15] of S. mahagoni were investigated earlier but analgesic and anti-diarrheal activity has not yet been reported. Therefore the present study was carried out to investigate possible analgesic and anti-diarrheal activity of Ethanolic extract of S. mahagoni leaves in experimental animal.

II. MATERIALS AND METHODS

Plant Material Collection and Extraction:
The leaves of S. mahagoni were collected from Banani Rail crossing, Dhaka, Bangladesh in October 2017. Then leaves were taken to Bangladesh National Herbarium to
confirm the specimen to be claimed *Swietenia mahagoni* and it was confirmed by the index code which was 41629. The leaves of *S. mahagoni* were shed dried (600 gm) which were grinded in the blender to make powder and mixed with ethanol (solvent) to make 1.8 L solution. After twelve days of soaking, a fine, white colored cotton was used for sieving. Filter paper was used to filter sieved solution to make 0.7L filtrate solution. Rotary evaporator was used to evaporate the solvent from the filtrate solution. The consistency of the final ethanol extract (28gm) of the leaves was semisolid. Then the extract was stored at 4°C before it was used.

**Experimental Animals:**

For the pharmacological investigation, 48 male and female Swiss albino mice weighed between 28 to 33 gm, were collected from animal Lab of ICDDR, Dhaka, Bangladesh. They were stored in standard polypropylene cages with controlled environmental conditions (55-65% relative humidity, 12 hours light/dark cycle and 24.0 ± 2°C temperature). Also sufficient amount of food and water were supplied all the time. Process of experiments where animals involved, were conducted in accordance to ethical guidelines of ICDDR, Dhaka, Bangladesh and approved by the Institutional Ethical Committee of ICDDR, Dhaka, Bangladesh.

**Drugs and Chemicals:**

Indomethacin and Loperamide were collected from Square pharmaceuticals Ltd., Bangladesh and Beximco pharmaceuticals Ltd., Bangladesh respectively. Analytical reagent grade chemicals were used in all cases.

**Acute Toxicity Test:**

The acute toxicity for ethanolic extracts of *Swietenia mahagoni* leaves was determined in mice according to the method of Lorke, 1983 [16] with slight modifications. Mice were divided into four groups of four mice each. Different doses of extracts (200, 400, 800, 1600 and 3200 mg/kg p.o.) were administered intraperitoneally and observed all groups over a period of 48 hour for signs of acute toxicity. The number of deaths within this period was recorded.

**Analgesic activity:**

To evaluate analgesic property of *S. mahagoni*, acetic acid-induced writhing method and formalin-induced hind paw-licking method were used.

**Acetic Acid Induced Writhing Method:**

The method of acetic acid-induced writhing test described by Ahmed et al was used to test analgesic activity of ethanolic leaf extract of *S. mahagoni* [17]. Mice were divided into four groups consisting of four Swiss albino mice in each. Group I labelled as control where vehicle (Saline water, 1 mL/kg body weight) was administered. In group II, Indomethacin was administered at the doses of 10 mg/kg which was used as a standard drug while group III and IV received the sample extract orally at two different doses (150 and 300 mg/kg). 20 µl of 5% formalin was injected into the dorsal surface of the right hind paw 60 min after administration of control, standard and test sample. The mice were observed for 30 min after the injection of formalin and the amount of time spent licking the injected hind paw was recorded. The first 5 min post formalin injection is referred to as the early phase and the period between 15 and 30 min as the late phase. Each mouse of all groups were observed individually for counting the number of licking they made in first 5 minutes and 20-30 minutes after the administration of formalin.

**Anti-diarrheal property**

**Castor-oil induced diarrhea model:**

Anti-diarrheal activity of the plant extract is determined by using the method described by Jebunnessa et al [20]. Sixteen mice were taken and divided into four groups. Vehicle (Saline water, 1 mL/kg body weight) was administered in Group I served as control while Group II was administered with the standard anti-diarrheal drug Loperamide at a dose of 5 mg/kg body weight. Crude leaf extracts were given to Group III and IV at the doses of 250 mg/kg and 500 mg/kg respectively. After one hour, castor oil was administered to all mice at a dose of 0.5ml/mice. All mice were kept in separate metabolic cages with a transparent plastic container beneath the cage to collect feces. Each mouse of all groups was observed individually for counting the number of feces for 5 hour.

**Statistical analysis:**

The data were presented as mean ± SEM (n=4). Results were analysed by one way analysis of variance (ANOVA) followed by Dunnett’s t-test. Probability (P) value of 0.05 or less (P<0.05) was considered as significant. Here a P≤0.001, b P<0.01 and c P<0.05 compared to control.

**III. RESULTS**

**Analgesic activity**

**Acetic acid induced writhing test:**

In acetic acid-induced writhing test, the plant extract at a dose of 200 mg/kg significantly reduced the number of writhing. Standard drug, Indomethacin showed highest percentage of inhibition (77.19%) at the dose of 10 mg/kg body weight. A dose of 100 mg/kg of the extract showed no significant inhibition of acetic acid induced writhing.

**Formalin induced hind paw-licking method:**

The test was performed using the method described by Hunskaar and Hole [19]. Mice were divided into four groups consisting of four in each group. Vehicle (Saline water, 10 mL/kg body weight) was administered in Group I labelled as control group and standard drug. Indomethacin was administered at the doses of 10 mg/kg in group II. In group III and IV, sample extract administered orally at two different doses (150 and 300 mg/kg). 20 µl of 5% formalin was injected into the dorsal surface of the right hind paw 60 min after administration of control, standard and test sample. The mice were observed for 30 min after the injection of formalin and the amount of time spent licking the injected hind paw was recorded. The first 5 min post formalin injection is referred to as the early phase and the period between 15 and 30 min as the late phase. Each mouse of all groups were observed individually for counting the number of licking they made in first 5 minutes and 20-30 minutes after the administration of formalin.
**Formalin induced hind paw-licking test:**

In early and late phase of formalin induced hind paw licking test, the administration of standard drug, Indomethacin inhibited 76.92% and 58.14% licking response respectively which are statistically significant (\(P \leq 0.001\) and \(P \leq 0.05\) respectively). The inhibition of licking response by ethanolic extract of \(S.\) mahagony was 23.85% at 150mg/kg dose and significant (\(P \leq 0.001\)) inhibition of 43.08% was found at 300mg/kg dose during the early phase. In the late phase of formalin test, the administration of ethanolic extract showed 23.26% inhibition at 150 mg/kg dose which is statistically significant (\(P \leq 0.05\)) as compared to the control group and 34.88% inhibition at 300 mg/kg dose.

**Anti-diarrheal activity:**

In the castor oil-induced diarrhea experiment, the 250 mg/kg extract of \(S.\) mahagony decreased number of defection which was significant for soft and watery stool (\(^bP \leq 0.05\) and \(^bP \leq 0.001\) for respectively) when compared to the control group and showed 88.89% inhibition of defection. Likewise, 500 mg/kg showed 94.44% inhibition of defection which was similar as standard control (Loperamide) and also reduced number of defection which was significant for hard, soft and watery stool.

Fig. 4 Anti-diarrheal effects of ethanolic extract of S. mahagony leaves

**IV. DISCUSSIONS**

Unpleasant sensory and emotional experience associated with actual or potential tissue damage is officially defined as pain. It proactively warns signal against disturbances of the body [21]. Acetic acid causes pain and localized inflammation by the action of prostacyclines and prostaglandin-E (PG-E) production which cause a sensation of sharp localized pain by stimulating the Aβ-fibres. It also induces the increased level of PGE2 and PGF2α in the peritoneal fluid which is responsible for pain production. Various peripherally acting analgesic drugs such as ibuprofen, indomethacin, aspirin and diclofenac sodium have shown inhibition to acid induced writhing by inhibiting the synthesis of prostaglandin. Hence, analgesic effect of an agent can be defined by the reduction in the number of writhing through the inhibition of prostaglandin synthesis [22]. The ethanolic leaf extract of *S. mahagony* showed significant ($^a P<0.001$) inhibition at 200 mg/kg dose as compared to control group which suggests that the reduction of pain by the inhibition of prostaglandin synthesis may be due to the presence of analgesic properties in the extract.

The involvement of either central or peripheral activity can not be confirmed only with this test [23]. Therefore, formalin test is usually carried out along with acetic acid-induced writhing test to distinguish between peripheral and central pain. The formalin model was developed to assess pain and evaluate analgesic drugs in laboratory animals. In this test, pain-related behaviors are determined by two temporally distinct phases. In the first phase of pain, formalin has been reported to activate nociceptors and primary afferent fibers through the release of bradykinin and trachykinins. In the second phase, histamine, serotonin, prostaglandin and excitatory amino acids are released due to an inflammatory reaction by tissue injury. The first phase is inhibited by opioid analgesics whereas the second phase is inhibited by non-steroidal anti-inflammatory drugs and opioid analgesics [24]. *S. mahagony* leaves showed maximum pain inhibition of 43.08% at 300mg/kg dose whereas Indomethacin showed 76.92% pain inhibition in early phase of formalin induced hind paw-licking method. In late phase, *S. mahagony* leaves showed 34.88% pain inhibition at 300 mg/kg dose whereas Indomethacin showed 58.14 % pain inhibition. The findings suggest that the plant extract not only inhibited the production of prostaglandin but also inhibited the activation of primary afferent fibers by formalin. The study findings showed that ethanolic extract of *S. mahagony* possess analgesic activity in the two analgesic models. The extract showed dose dependent inhibition with high doses of the extract showing a significant percentage of inhibition.

Diarrhea results from an imbalance between the absorptive and secretory mechanisms in the intestinal tract accompanied by quick resulting in an excess loss of fluid in the faeces. In some diarrhoea the secretory component predominates while other diarrhoea is characterized by hypermotility. For evaluating the antidiarrheal property of drugs, castor oil induced diarrhea model is commonly used. Diarrhoea is caused by the active metabolite of castor oil which is called ricinoleic acid [25, 26] that stimulates peristaltic activity in the small intestine, leading to changes in the electrolyte permeability of the intestinal mucosa. This sequence of events leads to the release of prostaglandins which stimulates motility and secretion thus reduces the absorption of sodium and potassium ions [27].

The ethanolic leaf extract of *S. mahagony* showed significant antidiarrheal activity (94.44%) at 500 mg/kg dose which was similar to that of the standard drug loperamide (5 mg/kg). It is probable that the extracts were able to inhibit electrolyte permeability to the intestine through the inhibition of prostaglandin release. Accumulation of intestinal fluid is suppressed by the ethanolic extract of plant which might also inhibit gastrointestinal functions [27]. Membrane bound enzyme Na⁺ and K⁺ ATPase has been related to sodium and potassium transport in the intestine. During diarrheal conditions, Na⁺ and K⁺ ATPase are decreased which relates to an interruption in the normal water and electrolyte absorption. The activity of Na⁺ and K⁺ ATPase might be affected by the decrease of water along with Na⁺ accumulation. The stimulated fluid, Na⁺ and K⁺ secretion which are induced by

the castor oil were inhibited in the extracts by a dose dependent manner.

Earlier studies indicated that anti-diarrheal properties of medicinal plants were mostly due to tannins, alkaloids, saponins, flavonoids, sterol and triterpenes [27]. The anti-diarrheal property of the extract of *S. mahagoni* found in the present study could be due to the presence of tannins, alkaloids, saponins, flavonoids, steroids in this plant [28-29].

V. CONCLUSION

In this current research work it was tried to evaluate the analgesic and anti-diarrheal properties of *S. mahagoni*. The results of this investigation shown that ethanolic extract of *S. mahagoni* possessed significant analgesic and anti-diarrheal properties. There is a need for a further research to be carried out to fractionate and purify the extract, in order to find out the constituents responsible for the analgesic and anti-diarrheal activities of *S. mahagoni*.

VI. ACKNOWLEDGEMENT

We greatly acknowledge the gracious help of the authority of animal Lab of ICDDR,B, Dhaka, Bangladesh for providing experimental animals. Thanks are due to Pritam Saha, Md. Jinat Ullah for their technical support.

VII. CONFLICT OF INTEREST STATEMENT

We declare that we have no conflict of interest.
